

# Week 3 Lab Report

Control Flow & Functions · Broken Records Summary

## The Three Broken Records

Out of the 40 students in `week3_students.csv`, 3 records had a score that could not be read as a number. They were found automatically while the pipeline tried to convert every score to an integer:

- **AUCA008** — the score field was left blank (empty value).
- **AUCA020** — the score field was also left blank (empty value).
- **AUCA032** — the score field contained the text "absent" instead of a number.

## How the Code Survived Them

Each row of the file was read one at a time, and the score column was passed through `int(parts[7])` inside a `try/except` block. When a score converted successfully, it was added to the running total and counted as valid. When it did not (because it was blank or the word "absent"), Python raised a `ValueError`, which the code caught instead of crashing. The student's ID was then saved to a separate `bad_ids` list, and the row was excluded from the average, pass/fail counts, and the top-student and district calculations.

This meant the program never stopped running, it simply kept two clean counters throughout: 37 valid scores and 3 bad ones, with the 3 flagged IDs printed out so they could be checked and fixed by hand later rather than silently lost.

## Result

Valid records: 37 | Bad records: 3 | Broken IDs: AUCA008, AUCA020, AUCA032
